

Course 2 - Looking at some Distributions

UCLA - Econ 19 - Fall 2018

François Geerolf

Contents

1	Bell-Shaped Distributions	1
1.1	Natural Sciences	1
1.2	Some maths	2
1.3	Google Sheets	2
2	Pareto Distributions	2
2.1	Maths of Pareto	2
2.2	Data on cities using Google Sheets	3
2.3	Data on cities using R Statistical software	3

During this course, we shall try to understand a technical passage in Rosen [1983]’s *The American Scholar* piece:

Of particular interest here is an observation, first studied systematically by the great Italian economist Vilfredo Pareto in the late nineteenth century, that the distribution of income contains an unusually large proportion of top earners: that is, among the rich rather than the poor. A visual image will perhaps clarify what is meant by “unusual” in this connection. Imagine a graph plotting IQ scores on the horizontal and the frequency of scores on the vertical. The result is a familiar bell-shaped curve. The peak of the bell occurs at a score arbitrarily scaled at 100 and the curve falls symmetrically on either side of 100. Now picture a similar graph, except with earnings on the horizontal. The resulting curve is unbalanced and nonsymmetrical - a bell that is definitely out of whack. To the left of the modal (peak) value it appears much like the IQ frequency curve. However, to the right of the mode it does not fall as fast as it does to the left. It looks as if someone had stood at the right end of the curve, placed it over his back like a rope, and dragged and stretched it out a very long distance. The upper or right-hand tail of the distribution of income is much thicker than the lower, left-hand tail. The extra weight on the right lends a certain skewness to the distribution of income. What this comes down to is that the distribution of earnings is far from proportionate to the distribution of ability. Amazingly, Pareto’s observations have been qualitatively duplicated in virtually every era of every society for which data on income distributions can be found.

There are a couple of technical terms in this passage which we will make an effort at trying to elucidate:

1. “Imagine a graph plotting IQ scores on the horizontal and the frequency of scores on the vertical. The result is a familiar bell-shaped curve.” Section

1 Bell-Shaped Distributions

1.1 Natural Sciences

```
height <- read.csv("https://raw.githubusercontent.com/hadley/r4ds/master/data/heights.csv")
```

Figure 1: BELL SHAPED CURVE

1.2 Some maths

The Bell shape curve is defined by a density function given by:

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right).$$

1.3 Google Sheets

Here is a link to the Google Sheets that we created in order to look at the Gaussian distribution. In particular, we were able to plot the density function of a Normal Distribution with $\mu = 0$ and $\sigma = 1$, using the formula above.

2 Pareto Distributions

2.1 Maths of Pareto

A key feature of the Pareto distribution is that the density distribution does not go as fast to 0 as x becomes large. If x is population, this means that there are relatively many cities with a large size. Similarly, there are relatively many incomes that are much larger than the mean. The Pareto Distribution is in fact defined by:

$$f(x) = a \frac{x_m^a}{x^{a+1}}.$$

For the cumulative distribution function, this implies:

$$1 - F(x) = \left(\frac{x_m}{x}\right)^a.$$

City Size Distribution: Size-Rank Log-Log Plot

Figure 2: CITY SIZE DISTRIBUTION

2.2 Data on cities using Google Sheets

We have used this Google Sheet in order to plot the city size distribution of cities.

We note that the result is something that is close to a linear relationship, suggestive of Pareto like behavior.

2.3 Data on cities using R Statistical software

```
pklist <- c("tidyverse", "rvest")
source("https://fgeerolf.github.io/code/load-packages.R")

data.on.cities <- "https://en.wikipedia.org/wiki/List_of_United_States_cities_by_population" %>%
  read_html %>%
  html_table(header = TRUE, fill = TRUE)

data.on.cities[[5]][,c(1:4)] %>%
  as.tibble
```

```
## # A tibble: 311 x 4
##   `2017rank` City      `State[5]` `2017estimate`
##   <int> <chr>      <chr>      <chr>
## 1      1 New York[6] New York    8,622,698
## 2      2 Los Angeles California 3,999,759
## 3      3 Chicago      Illinois   2,716,450
## 4      4 Houston[7] Texas      2,312,717
## 5      5 Phoenix      Arizona    1,626,078
## 6      6 Philadelphia[8] Pennsylvania 1,580,863
## 7      7 San Antonio Texas       1,511,946
## 8      8 San Diego      California 1,419,516
```

```
## 9          9 Dallas      Texas      1,341,075
## 10         10 San Jose    California 1,035,317
## # ... with 301 more rows
```
